MCQs Answer Sheet

Instructions for Answering MCQs:

- Attempt MCQs on Bubble Sheet only otherwise will not be checked.
- Fill the Roll Number without dash in the provided field and replacing the character with respective digits (L=0). For Example: 22L-9980 => 2209980)
- Cutting, overwriting, multiple answers, or not correctly filling the circle would be considered incorrect and choose the most relevant options.

[CLO 1: Identify key components behind the design of blockchain and to understand the types of applications that best fit the model of blockchain]

[Part-A]

Q1: Multiple Choice Questions (MCQs)

[25 marks]

1. A block in a blockchain contains:
 - a. Only transactions
 - b. Transactions, hash, and metadata
 - c. Only the hash of the previous block
 - d. IP addresses of users
 - e. Smart contract source code
2. The immutability of blockchain data is ensured by:
 - a. Password protection
 - b. Cryptographic hashing and linking blocks
 - c. Anti-virus software
 - d. Cloud storage
 - e. Two-factor authentication
3. What happens if someone changes a previous block in the chain?
 - a. Network ignores it
 - b. Only that block is updated
 - c. Hash mismatch invalidates the chain
 - d. Wallets reset
 - e. Nothing happens
4. Blockchain operates in which type of network?
 - a. Peer-to-peer
 - b. Ring topology
 - c. Star topology
 - d. Centralized client-server
 - e. Mesh-based FTP
5. Bitcoin mining rewards reduce after every _____ approximately:
 - a. 2100 blocks
 - b. 21000 blocks
 - c. 10000 blocks
 - d. 10 million blocks
 - e. 210000 blocks
6. Which of the following stores your private keys?
 - a. Node
 - b. Wallet
 - c. Miner
 - d. Block
 - e. API
7. The smallest unit of Ethereum is called:
 - a. Ether
 - b. Wei
 - c. Microbitcoin
 - d. Satoshi
 - e. Bit

National University of Computer and Emerging Sciences

Lahore Campus

8. The Bitcoin blockchain is:
 - a. Private
 - b. Hybrid
 - c. Public and permissionless
 - d. Sidechain only
 - e. Centralized
9. What happens when two miners mine a block at the same time?
 - a. Both are accepted
 - b. The chain splits forever
 - c. Bitcoin stops functioning
 - d. The longer chain eventually wins
 - e. The last block is deleted
10. A smart contract:
 - a. Is manually executed
 - b. Needs admin approval
 - c. Executes based on conditions written in code
 - d. Works like a PDF
 - e. Is stored on USB
11. Which of the following best explains the role of the Merkle root in a Bitcoin block?
 - a. It encrypts all transactions for privacy
 - b. It stores the hash of the previous block
 - c. It tracks the balance of all addresses
 - d. It summarizes all transactions for efficient verification
 - e. It controls the mining difficulty
12. What role does the difficulty target play in Bitcoin's Proof of Work system?
 - a. It determines how many nodes are allowed to mine
 - b. It adjusts transaction fees dynamically
 - c. It regulates the average block mining time
 - d. It defines the maximum allowed block size
 - e. It encrypts block data
13. Alice is sending a Bitcoin transaction to Bob. She sets a very low transaction fee. What is the most likely outcome?
 - a. The transaction is canceled by the sender
 - b. The transaction is delayed or possibly ignored by miners
 - c. The transaction is processed immediately
 - d. The blockchain auto-adjusts the fee
 - e. Bob must pay the rest of the fee
14. A developer writes a smart contract with a public function that transfers ETH without checking the sender's identity. What risk does this introduce?
 - a. The contract will auto-delete
 - b. Anyone could call the function and steal ETH
 - c. It will fail due to missing ABI
 - d. It uses too much gas
 - e. Only the miner can access the function
15. What is the main purpose of a smart contract?
 - a. To send emails
 - b. To automate agreements
 - c. To mine cryptocurrency
 - d. To design websites
 - e. To store images

National University of Computer and Emerging Sciences

Lahore Campus

16. A DApp developer deploys a contract but later finds a bug. They forgot to include an upgrade mechanism. What is their best option now?
 - a. Edit the deployed code directly
 - b. Use selfdestruct() to recover Ether
 - c. Contact miners to revert the block
 - d. Roll back the blockchain
 - e. Redeploy a fixed version and redirect users manually
17. A user imports a wallet using a 12-word seed phrase on a new phone. What happens to their funds?
 - a. The wallet creates a new private key
 - b. The funds are lost permanently
 - c. The wallet becomes invalid
 - d. The address changes but the balance remains
 - e. The same private key and funds are restored
18. A Bitcoin user tries to send coins from an address, but the wallet shows "insufficient inputs". What is the likely cause?
 - a. The mempool is full
 - b. The address uses Proof of Stake
 - c. The required UTXOs are already spent
 - d. The transaction fee is too high
 - e. The transaction is too old
19. Smart contracts execute automatically when:
 - a. The government approves them
 - b. A lawyer signs them
 - c. Predefined conditions are met
 - d. The blockchain is restarted
 - e. The miner requests execution
20. Which of the following is required to interact with a smart contract?
 - a. Internet connection
 - b. Blockchain network access
 - c. Cryptocurrency wallet
 - d. All of the above
 - e. None of the above
21. Which of the following is NOT a feature of smart contracts?
 - a. Automation
 - b. Transparency
 - c. Central control
 - d. Immutability
 - e. Deterministic execution
22. A smart contract can manage:
 - a. Digital assets
 - b. Voting systems
 - c. Token transfers
 - d. Escrow services
 - e. All of the above
23. In Bitcoin, what does "6 confirmations" mean?
 - a. Six miners approved the transaction
 - b. The transaction appears in six different wallets
 - c. Six blocks have been mined after the block containing the transaction
 - d. Six nodes verified the transaction
 - e. The transaction fee was multiplied by six
24. A transaction with 0 confirmations is also called:

National University of Computer and Emerging Sciences

Lahore Campus

- a. Confirmed transaction
 - b. Coinbase transaction
 - c. Mempool transaction
 - d. Finalized transaction
 - e. Orphan transaction
25. A miner in Bitcoin is responsible for:
- a. Verifying Transactions
 - b. creating blocks
 - c. Storing Users passwords
 - d. Setting exchange prices
 - e. Both A and B

Solution:

1. b 2. b 3. c 4. a 5. e 6. b 7. b 8. c 9. d 10. c 11. d 12. c 13. b 14. b 15. b
16. e 17. e 18. c 19. c 20. d 21. c 22. e 23. c 24. c 25. e

[Part-B]

Scenario: A group of Bitcoin miners begins censoring transactions from specific wallets due to political pressure. These transactions are not included in any blocks.

[CLO 2: Understand why blockchain is considered “secure” and “immutable” and the design of Bitcoin and other cryptocurrencies]

Q2: Can miners choose to exclude certain transactions? Why or why not?

[6 marks]

Yes, miners can technically choose to exclude certain transactions from the blocks they produce, but this goes against the decentralized and neutral ethos of Bitcoin.

Explanation:

1. Miner Autonomy:

Each miner independently selects which transactions to include in their block. They generally prioritize transactions offering the **highest fees** (in satoshis per byte).

Hence, a miner *can* omit transactions from specific wallets.

2. Protocol Perspective:

The **Bitcoin protocol** does **not enforce inclusion of all valid transactions**—only that transactions follow consensus rules (valid signatures, no double spend, etc.).

Exclusion does not make a block invalid.

3. Decentralization Counter-Force:

However, censorship is difficult to sustain because:

- Other miners can include the censored transactions in their own blocks.
- The longest-chain rule incentivizes inclusion of all profitable (fee-paying) transactions.
- Users can increase fees to attract inclusion (“fee market pressure”).

4. Economic and Reputational Cost:

Persistent censorship lowers miners’ profitability and may lead to **loss of trust** and **network forks** if the community views them as acting maliciously.

[CLO 2: Understand why blockchain is considered “secure” and “immutable” and the design of Bitcoin and other cryptocurrencies]

Q3: Propose and explain potential strategies that could reduce or prevent miner-driven transaction censorship in Proof of Work (PoW) blockchain networks.

[6 marks]

Several mechanisms can reduce or neutralize censorship attempts by miners in Proof-of-Work (PoW) systems like Bitcoin:

1. Decentralization of Mining Power

- Encourage many independent miners and pool diversity to prevent cartel behavior.
- Discourage concentration through anti-pool protocols (e.g., Stratum V2 with job negotiation).

National University of Computer and Emerging Sciences

Lahore Campus

2 Stratum V2 Protocol

- Allows individual miners to choose transactions for inclusion rather than pool operators, preventing centralized control over block templates.

3 Fee-based Incentives

- Users can increase transaction fees to make censorship economically irrational.
- Higher-fee transactions attract miners who prioritize revenue.

4 Relay Networks and Mempool Diversity

- Use multiple relay networks (FIBRE, Falcon) to propagate transactions quickly so that censored transactions reach *non-censoring* miners.

5 “Inclusion Proof” Mechanisms

- Future Bitcoin research explores proof-of-inclusion or censorship-resistant relay nodes to track missing transactions.

6 Soft Governance / Social Layer

- The community can soft-fork or penalize identified censoring entities by changing mining pools or adopting new protocols.

Scenario: A large mining pool controlling 30% of the network hash power suddenly goes offline due to regulatory action.

[CLO 2: Understand why blockchain is considered “secure” and “immutable” and the design of Bitcoin and other cryptocurrencies]

Q4: How does Bitcoin’s difficulty adjustment mechanism respond?

[6 marks]

Bitcoin adjusts mining difficulty **every 2016 blocks** (approximately every 2 weeks under normal conditions).

Because blocks are now being mined more slowly:

- It will take **longer than two weeks** to mine the next 2016 blocks.
- When the adjustment occurs, the protocol automatically **reduces the mining difficulty**.
- The goal is to bring the average block time back to **10 minutes**.

The difficulty adjusts proportionally based on how long the previous 2016 blocks took to mine.

After adjustment:

National University of Computer and Emerging Sciences

Lahore Campus

- Block time stabilizes near 10 minutes again (assuming hash rate remains constant).

[CLO 2: Understand why blockchain is considered “secure” and “immutable” and the design of Bitcoin and other cryptocurrencies]

Q5: Will network security increase or decrease? Explain.

[6 marks]

Short-term: Security decreases.

Reason:

- Lower total hash power means less computational cost to attack the network.
- A malicious actor now needs fewer resources to perform attacks (e.g., double spending).
- The threshold for a 51% attack becomes easier to reach because total network hash rate is lower.

Long-term:

If miners relocate and hash power returns, security restores. After difficulty adjustment, block timing stabilizes, but overall security depends on total hash power, not difficulty alone.
